INVESTIGATIONS OF PLANT REACTION TO THE MAIZE DWARF MOSAIC VIRUS - 1965

By Frank A. Loeffel and E. M. Johnson

Five groups of material were evaluated in 1965 for plant reaction to the maize dwarf mosaic virus (MDM) at three testing locations in Kentucky where the virus was present. Two of the locations, Augusta and Vanceburg, are in the Ohio river valley. The Frankfort location is in the Kentucky river valley. Severe disease conditions were present naturally at each evaluation site in 1965 as well as in the two previous years. Heavy infestations of Johnsongrass were present at each location. Visual symptoms of virus were evident in the Johnsongrass at Frankfort when the trials were planted and within two weeks of planting at Augusta and Vanceburg. The cooperating farmers, the fertilizer used, and the dates of planting, virus rating, and harvest were as follows:

Location	Cooperator	Fertilizer	Date		
			Planting	Virus Rating	Harvest
Augusta	George and Paul Gearhart	320# NH ₄ NO ₃ 133# Superphosphate 133# Muritate of potash	5/17	8/19	10/16
Vanceburg	Alex Waters, Jr.	1000# 5-10-10	5/18	8/18	11/1
Frankfort	Mason and Ralph Bates	300# NH ₄ NO ₃ 100# Muritate of potash	5/14	8/23	-----

Evaluation of MDM virus reaction was made on:

1. Commercial hybrids being compared in the Kentucky Hybrid Corn Performance test,
2. Experimental single- and double-cross hybrids from the University of Kentucky,
3. Commercial and experimental hybrids from industry,
4. A 10-line diallel of yellow single-cross hybrids, and
5. 144 inbred lines from state and federal sources.

The four groups of hybrids were compared in replicated trials in 2 x 5 hill plots at a population of 15,680 plants per acre. Data were recorded in respect to yield, root and stalk lodging, ear height, harvest moisture and harvest stand in addition to MDM virus ratings. The harvest stand of extremely susceptible hybrids tends to be low owing to the total disintegration of prematurely killed plants by harvest. Comparable stands were present at thinning. Only MDM virus ratings were recorded on the inbred line study which was grown at Vanceburg and Frankfort in two replications per location.

A scale of 1 to 9 was used in rating plants. A rating of 1 indicates no injury and a rating of 9 complete susceptibility. Ratings were taken on a plot basis.

The distribution of MDM virus in Kentucky as confirmed by mechanical transmission studies appears in Fig. 1. Samples of diseased corn having symptoms of virus injury, received by the Plant Diagnostic Laboratory, Department of Plant Pathology, from

corn producers and county extension agents, were the source for the mechanical transmission studies. All mechanical transmission tests on wheat were negative. No estimates of disease severity, extent of affected area in each county, or loss in production can be made.

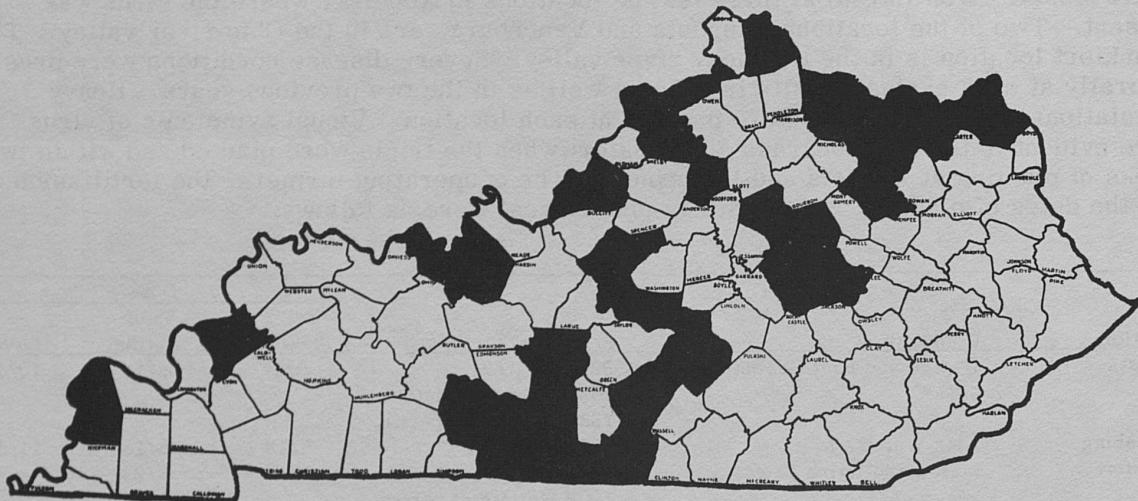

FIG. 1.--DISTRIBUTION OF MDM VIRUS IN KENTUCKY IN 1965, CONFIRMED BY MECHANICAL TRANSMISSION.

A summary of agronomic data recorded on commercial hybrids entered in the Kentucky Hybrid Corn Performance Test and evaluated under MDM virus conditions is in Table 1. The hybrids are ranked in order of increasing susceptibility within endosperm color groups. Data on experimental hybrids from the University of Kentucky and from industry are summarized in Tables 2 and 4. The pedigrees of the University of Kentucky experimental hybrids are listed in Table 3. The relationship of the MDM virus rating and the yield in pounds per acre in each of the seven replicated virus experiments is summarized in Table 5. A striking relationship exists between the MDM virus rating and yield. A similar relation exists between virus rating and standing ability.

Agronomic data from a diallel set of yellow single crosses is summarized in Tables 6, 7 and 8. With the exception of inbred Ky 36-11 a close relationship exists between the rating of inbred lines per se and in single cross combinations.

Average MDM virus ratings of inbred lines evaluated at Vanceburg and Frankfort, Ky., are summarized in Table 9.

1/ Data obtained from C. O. Grogan, State College, Mississippi. Values are a weighted index of individual plant ratings taken on a scale of 1 to 5.
 1, no symptoms; 5, more than $\frac{1}{2}$ of stalk below the upper ear and all above the upper ear with symptoms.
