

# KENTUCKY HYBRID CORN PERFORMANCE TEST — 1973

C. G. PONELEIT and K. O. EVANS

PROGRESS REPORT 212

UNIVERSITY OF KENTUCKY  
COLLEGE OF AGRICULTURE  
Agricultural Experiment Station  
Department of Agronomy  
Lexington

## TESTING LOCATIONS OF THE 1973 KENTUCKY HYBRID CORN PERFORMANCE TRIALS

(Locations identified in Table 3.)

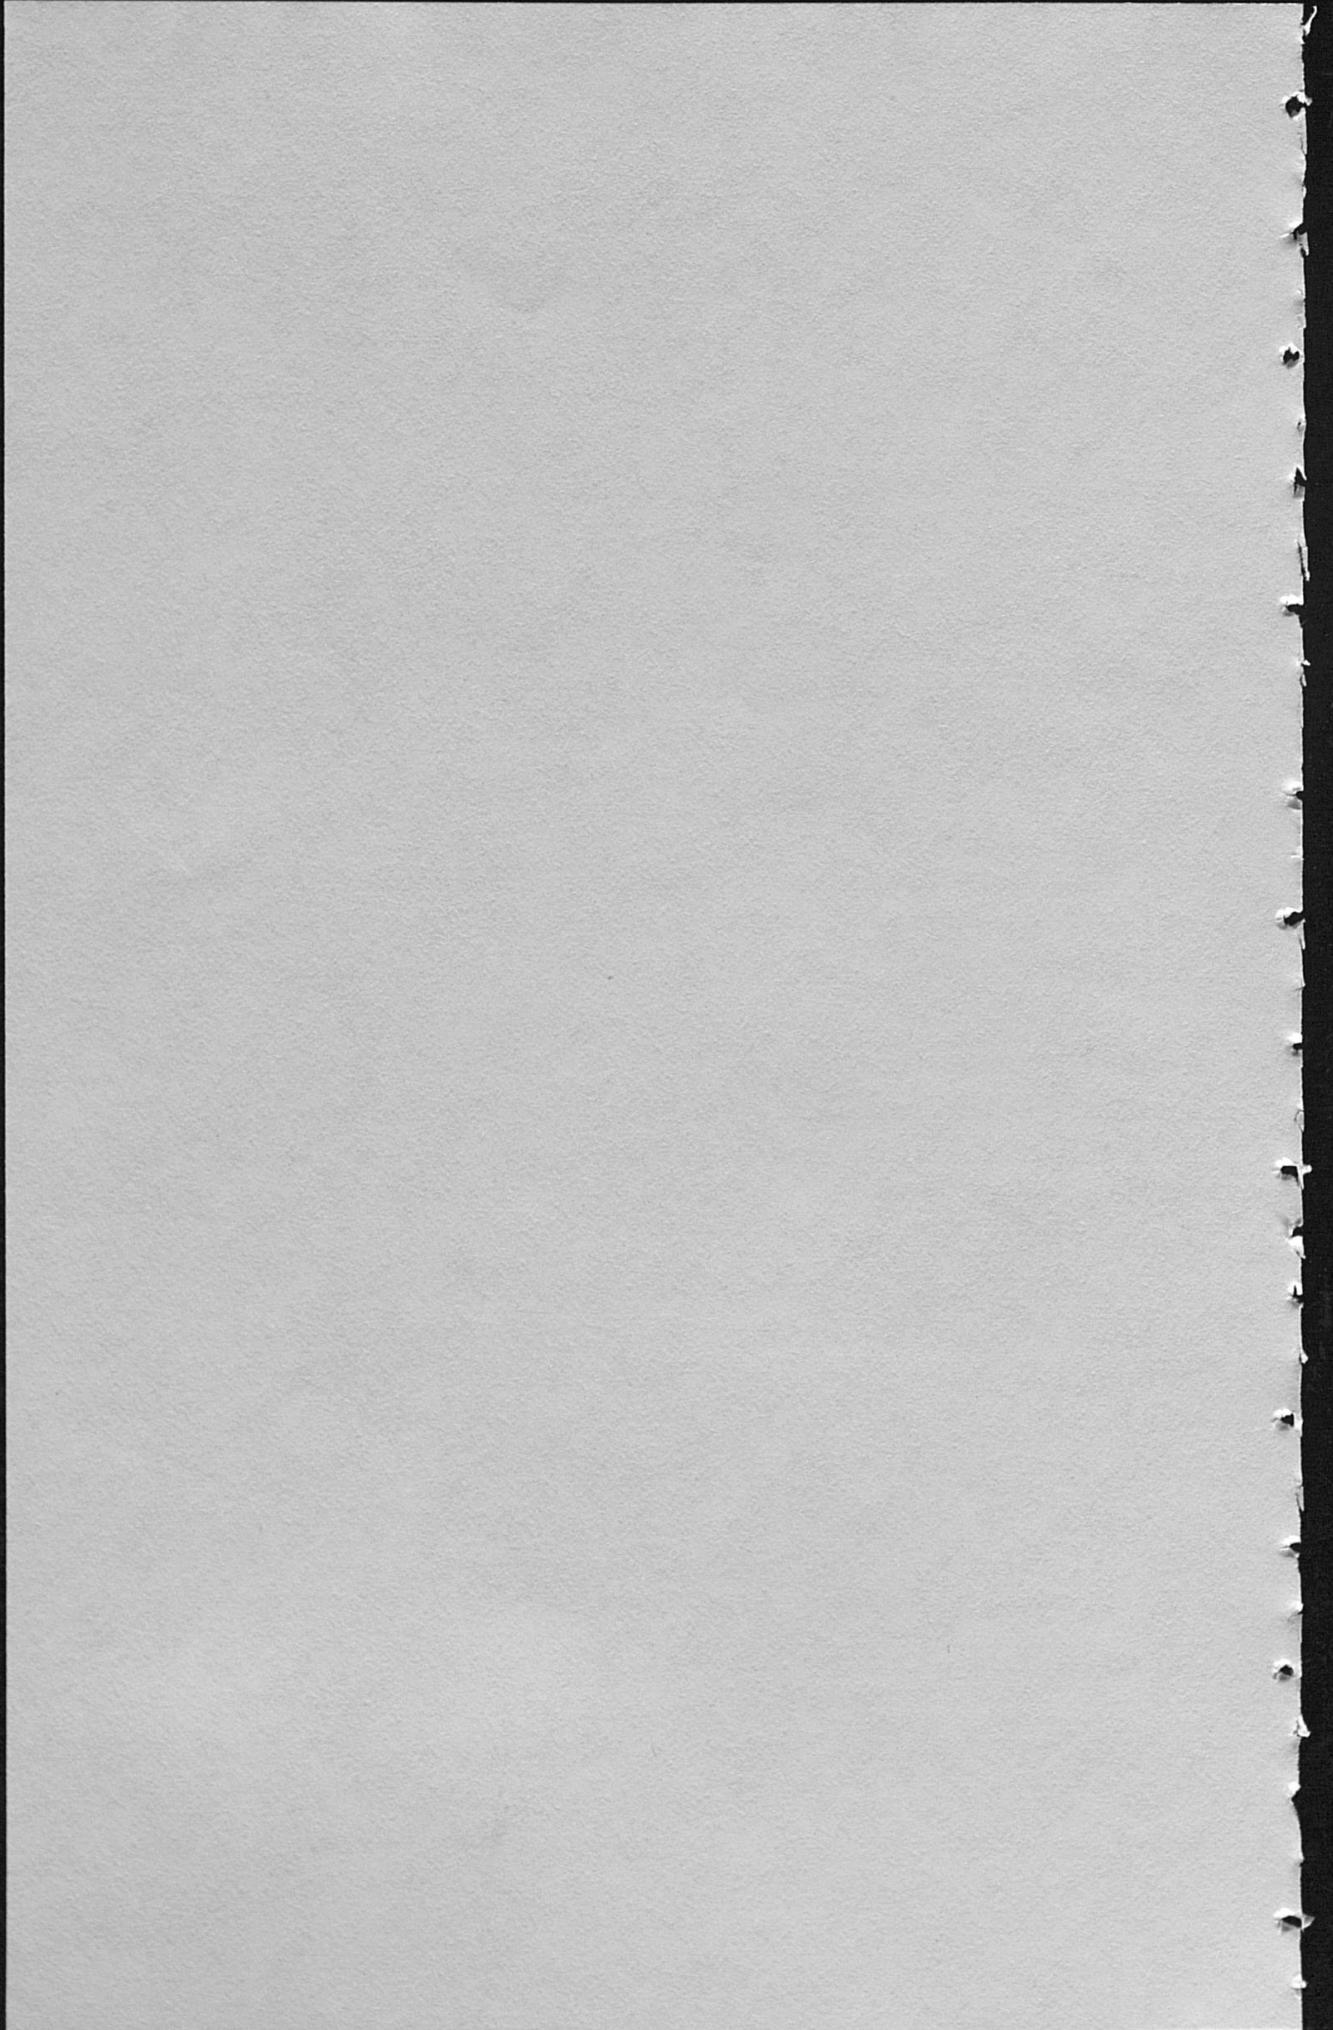

### ACKNOWLEDGMENTS

The authors are grateful to Mr. John Byers and Dr. Paul Cornelius, Department of Agronomy, for their assistance in summarizing the results presented in this progress report. Also acknowledgments are made to the following persons who aided in the conduct of this year's performance test:

Dr. Morris Bitzer, Extension Specialist in Grain Crops, Lexington.  
Dr. James Herbek, Extension Specialist in Grain Crops, West Kentucky Substation, Princeton.  
Charles Tutt, Research Specialist, West Kentucky Substation, Princeton.  
Harvey Mitchell, Superintendent, West Kentucky Substation, Princeton.  
George A. Armstrong, Superintendent, Robinson Substation, Quicksand.  
C. E. Wyatt, Area Extension Agent, Mayfield.  
John Kavanaugh, Area Extension Agent, Hartford.  
William Hendrick, Extension Agent, Henderson.  
Don Kessler, Extension Agent, Franklin.  
Jack Snyder, Extension Agent, Elizabethtown.  
Clarence Bayes, Extension Agent, Irvine.

# Kentucky Hybrid Corn Performance Test 1973

*By C. G. Poneleit and K. O. Evans*

The objective of the Kentucky Hybrid Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. This information can be a valuable aid to corn growers as they select hybrids for use in the following season.

## PRESENTATION OF DATA

Complete 1973 data are presented for each location where a test was conducted. Two-year and three-year yield averages (1972 and 1973 data) are also included in each of these tables. Readers are encouraged to consider these multiple-year averages and the average over all locations in 1973 (Tables 12, 13, and 14) since these are better estimates of a hybrid's relative yield ability than data gathered at one location in one year. Data from 1972 and 1971 are used in the 2- and 3-year summaries over all locations in Tables 13 and 14.

Comparisons between yields or other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures do not provide a suitable comparison between a hybrid grown at one location and population with another hybrid grown at a different location and population.

## TESTING PROCEDURE

### SELECTION OF HYBRIDS

Ky 105 and Ky 5921W (Table 1) were again included as check varieties to compare performance over years. Seed of each commercial hybrid (Table 2) was obtained from dealers in Kentucky whenever possible.

Those hybrids grown in the corn virus test and high population tests are indicated in column 2 of Table 2. The hybrid corn companies were asked to nominate those hybrids known to have virus resistance for inclusion in the virus test. Hybrids grown in the high population tests were also suggested by the parent company; thus, not all hybrids will appear in the virus or high-population test results.

#### **LOCATION OF TESTS**

The map on page 2 shows the location for each test. The Lexington and Princeton locations had both normal and high population tests, while all other locations had only the normal population. The Irvine site was specifically chosen for the presence of corn virus.

#### **CULTURAL PRACTICES**

The seedbed at each location except Elizabethtown and Franklin was prepared by conventional tillage methods. Fertilizer was applied as indicated by soil tests. The test at Elizabethtown was planted in a fescue sod and at Franklin in winter wheat, using recommended no-tillage practices. The test areas were treated with herbicide and supplemented by post-emergence cultivation when necessary. Table 3 shows the specific treatment for each location.

#### **EXPERIMENTAL DESIGN**

Uncontrollable variability of soil types, fertility, and other factors was sampled by using three replications of an appropriate balanced lattice design. A separate randomization was used for each location. Yields presented in Tables 4 through 22 are adjusted for block and replication differences when shown applicable by statistical analyses.

## **PLANTING**

All plots were planted with a two-row no-till corn planter modified for small plot work. The planter boxes were replaced by special planting cones which allowed planting of a specified number of kernels per plot. Each plot consisted of two rows 38 inches apart. Population was varied by planting different numbers of kernels per row. A normal population test had 20,000 kernels planted per acre, while the high population test had 26,000 kernels planted per acre.

## **HARVESTING**

All plots were harvested with a tractor-mounted one-row picker-sheller. Both rows of each two-row plot were picked, shelled, and the grain collected in a metal container. The grain weight and moisture content of each plot were then measured with a portable scale and moisture meter. Later, acre yields were calculated and adjusted to No. 2 corn at 15.5% moisture. Dropped ears were not gleaned from the plots. The number of plants remaining in each plot at harvest and the number of lodged plants were recorded immediately prior to harvest.

## **CORN VIRUS**

In addition to maize dwarf mosaic virus, a second virus has been found in Kentucky corn fields. Both the new virus and maize dwarf mosaic virus overwinter in Johnsongrass, and both are probably present in most areas where maize dwarf mosaic virus had previously been determined as the major disease. For this reason, the Irvine, Ky. test (Tables 20-22) will be referred to as the "corn virus test" with the understanding that resistance to both maize dwarf mosaic and the newly discovered virus is being evaluated.
