KENTUCKY HYBRID CORN PERFORMANCE TRIALS

ACKNOWLEDGMENTS

The authors gratefully acknowledge Mr. John Byers for his assistance in summarizing the results presented in this progress report. Also acknowledgments are made to the following persons who aided in the conduct of this year's performance test:

Charles Tutt, Research Specialist, West Kentucky Substation, Princeton.
Paul Appel, Superintendent, West Kentucky Substation, Princeton.
C. E. Wyatt, Area Extension Agent, Mayfield.
Stuart Brabent, Area Extension Agent, Henderson.
John Kavanaugh, Area Extension Agent, Hartford.
Clifton Taylor, Area Extension Agent, Franklin.
George Armstrong, Superintendent, Robinson Substation, Quicksand.
Dr. A. S. Williams, U. K. Department of Plant Pathology, Lexington.

KENTUCKY HYBRID CORN

PERFORMANCE TEST IN 1970

C. G. Poneleit and K. O. Evans

INTRODUCTION

The objective of the Kentucky Corn Performance Test is to provide unbiased performance estimates of hybrid seed corn sold in Kentucky. This information, hopefully, will aid farmers as they select hybrids for use in the following season.

In addition to the crop hazards expected during a normal crop season, the 1970 Kentucky corn crop was attacked by a devastating new race of Southern Corn Leaf Blight (Helminthosporium maydis). Summarized under the next major heading are some of the points that each corn grower should consider before purchasing seed corn for 1971.

SOUTHERN CORN LEAF BLIGHT

Occurrence and Symptoms

The new race of Helminthosporium maydis was first diagnosed in Kentucky during June 1970. It is extremely pathogenic on plants containing the Texas male-sterile cytoplasm. The disease is first noticed as light green flecks on the leaves; each of which eventually forms brownish lesion that can enlarge to $\frac{1}{2}$ inch long. Under ideal conditions the lesions will cover the entire leaf surface, causing death of susceptible plants.

Since the disease is likely to be a problem in 1971 also and since the best method of control is the use of resistant hybrids (those that do not have Texas male-sterile cytoplasms), the following suggestions should be used when buying seed for 1971.

Recommendations for 1971 Seed Corn Purchases

The University of Kentucky Agricultural Experiment Station recommends that seed corn for 1971 be purchased in the following order of priority:

1. A hybrid with 100% normal cytoplasm (N) that has performed well in past years' tests.
2. A hybrid with a blend of normal and Texas male-sterile cytoplasms (B) that has performed well in past years' tests.
3. F₂ or second generation seed of a proven normal cytoplasm hybrid.

These recommendations are based on the observations that susceptibility to Southern Leaf Blight of corn is associated with the

Texas male-sterile cytoplasm. Most normal cytoplasm hybrids appear resistant to this disease. Also, the 1970 test results presented in this report indicate that at least some blends approach the resistance level of completely normal cytoplasm hybrids.

F_2 or second generation seed has been given the third priority position because of the known reduction in yield potential of this type of seed. This yield reduction is independent of disease resistance and for 4X, 3X, and 2X hybrids is expected to average about 20, 25, and 30%, respectively. However, these figures are only averages based on previous studies of other hybrids. Actual yield reductions of individual hybrids could be much more severe.

Seed Labeling Requirements

All seed corn sold in Kentucky for the 1971 season must be labeled as to type of cytoplasm according to the Temporary Labeling Requirements for Corn Seed which was issued by the University of Kentucky, College of Agriculture, Division of Regulatory Services on November 10, 1970. These requirements state that seed corn shall show the identity and percentage of the cytoplasm in the seed lot on the front of the analysis tag or label. The symbols N, T, and B will be used to indicate 100% normal cytoplasm, 100% Texas male-sterile cytoplasm, and a mixture of normal and Texas male-sterile cytoplasms, respectively. The word, detasseled, does not guarantee that a hybrid will have normal cytoplasm and therefore cannot be accepted as assurance that a hybrid will have resistance to Southern Corn Leaf Blight.

If you have further questions about Southern Corn Leaf Blight or other items discussed in this report, please contact your County Agricultural Extension Agent.

TESTING PROCEDURE

Test procedures for 1970 were similar to those used in 1969 and are described in following portions of the text.

Selection of Hybrids

Ky 105 and Ky 5921W (Table 1) were included as check varieties. The commercial hybrids shown in Table 2 were selected from those being marketed in Kentucky. The hybrids included in the performance test were recommended by independent groups: (1) a committee of farmers with broad interests throughout the state and (2) the hybrid corn companies. The final selection of entries was made by the test personnel and the state grains specialist. Seed was obtained from dealers and processors throughout the state.

Following each entry in Table 2 are the letter(s) A, B, or C which indicate whether the hybrid was included in the performance test (7 locations), the preliminary screening test (2 locations), the MDM virus test (1 location), or a combination of 2 or 3 of these.

Location of Tests

The 1970 performance test locations were identical to the 1969 test locations. Each location sampled a different soil and climatic area of the state. The map on page 2 shows the location and Table 3 shows pertinent agronomic information for each test. The Lexington and Princeton locations had a normal and high population test as well as a screening test, which was initiated in 1970 to help identify promising additions to the larger performance test. The other test sites had only the normal population performance tests.

The Frankfort test site was specifically chosen for the presence of maize dwarf mosaic virus. The hybrid corn companies were asked to nominate only those hybrids that were known to have virus resistance.

Cultural Practices

The seedbed was prepared by conventional tillage methods at all locations. Fertilizer was applied as indicated by soil tests. The test areas were treated with herbicide and supplemented by post emergence cultivation when necessary. Table 3 shows the specific treatments for each location.

Experimental Design

Uncontrollable variability of soil types, fertility and other factors was sampled by using three replications of an 8 x 8 balanced lattice. A separate randomization was used for each location. Information presented in Tables 4 through 20 is adjusted for block and replication differences when shown applicable by statistical analyses.

Planting

All plots were planted with a conventional four-row corn planter modified for small plot work. The planter boxes were replaced by special planting heads to permit clean-out after planting each plot row. Each hybrid plot consisted of three side-by-side rows. The two outer rows bordered the middle row from competitive effects of neighboring hybrids and were not used for collection of data. The row width at all locations was 38 inches. Population was varied by altering combinations of row length and number of kernels per row.

Harvesting

All plots were harvested with a conventional tractor-mounted, one-row picker-sheller. The middle row of the 3-row plot was picked, shelled, and the grain collected in a metal container. The grain weight and moisture content of each plot were then measured and recorded on the harvesting equipment with a portable scale and moisture meter. Later, acre yields were calculated and adjusted to

No. 2 corn at 15.5% moisture. Only grain picked up by the harvesting equipment appears in the yield column of the following tables. Dropped or missed ears were not gleaned from the plot.

Maize Dwarf Mosaic Virus

Each hybrid in the Frankfort test (Tables 19 and 20) was rated for virus resistance on a 1-9 scale. A rating of 1 indicates complete resistance to the virus, while a rating of 9 indicates extreme susceptibility. The virus rating should be used in conjunction with yield performance for evaluating hybrids in the Frankfort test since the yields of the hybrids were noticeably influenced by severe lodging which may or may not have been caused by the virus disease.

Southern Corn Leaf Blight also attacked the hybrids in the virus test. Several of the hybrids are new and consequently were made by hand pollinations of normal cytoplasm stocks. These varieties undoubtedly had an extra yield advantage over the hybrids that had the leaf blight susceptible T cytoplasm. For this reason yield and virus ratings may be difficult to interpret.

Southern Corn Leaf Blight

Dr. A. S. Williams, State Agricultural Extension Plant Pathologist, rated the hybrids for leaf blight resistance at the Henderson, Hartford, and Franklin locations. Rating of visual leaf blight symptoms were made on a 0-9 scale with 0 indicating resistance (none or very few Southern Corn Leaf Blight lesions) and 9 indicating extremely susceptible (the entire plant was necrotic or dead). A summary of these ratings is presented in Table 21.

RESULTS

Due to the occurrence of a severe epiphytotic of Southern Leaf Blight of corn (Helminthosporium maydis), presentation of the 1970 data has been changed from past years' format. Multiple year averages have been omitted since we feel that averaging data from years that had no disease with data from 1970 would be of little value. This decision was based on the knowledge that most of the hybrids tested in 1970 possessed the susceptible Texas male-sterile cytoplasm and that much of the hybrid seed for use in 1971 and 1972 will contain the more resistant normal cytoplasm. However, several hybrids tested in 1970 were 100% N cytoplasm or a blend of N and T cytoplasms and the data presented for these varieties will be of interest.

We have also included data from preliminary screening tests at two locations which were initiated in 1970 to screen new entries for possible addition to our regular tests. These data are included since some of the hybrids, although they may be in short supply, had normal cytoplasms and could provide additional resistant seed for 1971.

In addition to the 1970 annual summaries for each location, we have included the 1969 summary over all non-virus locations and the 1969 MDM virus test summary. This is done because most of the hybrids tested in 1970 had the susceptible Texas male-sterile cytoplasm and the 1970 data will not be an accurate assessment of their true yield potential if they can be produced and sold as the more resistant normal cytoplasm versions for 1971. Therefore, the 1969 averages will be helpful when deciding among several hybrids that were susceptible in 1970 (T cytoplasm) but may be resistant for 1971 (N or B cytoplasm).

The plots in 1969 and 1970 were planted at 20,000 and 26,700 kernels per acre for the normal and high populations respectively and were not thinned. The percent stand indicated in each annual table, when multiplied by the number of kernels planted per acre, will be the actual plant population of that hybrid. A percent stand less than 100 would indicate some loss of plants owing to incomplete germination, seedling diseases or other factors. However, a stand reduction of 15% is not uncommon.

Comparisons between yields or other characters of any two or more hybrids should be made only with data from one table at a time. The testing procedures employed do not allow comparisons such as a hybrid grown at one location and population with another hybrid grown at a different location and population.

* Ratings for Southern Corn Leaf Blight (SCLB) on a 0-9 scale. 0 = no leaf lesion, 9 = dead or very severely damaged. The early ratings (8-11-70) were taken at Franklin and Hartford, Ky. and the late ratings (9-2-70) at Hartford and Henderson, Ky. by Dr. A. S. Williams, Department of Plant Pathology.

** 1 = Few diseased, shriveled kernels and no broken cobs in grain at harvest.
 2 = Moderate amounts of above factors.
 3 = Excessive amounts of above factors.
 Ratings in table represent the average over all non-virus locations.
